Type : Poster

The Structure of PaeDAH7PS: a Potentially Promiscuous Protein

Pseudomonas aeruginosa is an opportunistic human pathogen associated with the chronic infection of the lungs of Cystic Fibrosis patients – New Zealand's most common lethal genetic disease. *P. aeruginosa* has an innate resistance to antibiotics and concerns exist around the appearance of multi-drug resistant strains [1].

The shikimate pathway is responsible for the biosynthesis of key aromatic metabolites including the aromatic amino acids phenylalanine, tyrosine, and tryptophan; folic acid; and, in the case of *P. aeruginosa*, the toxic secondary metabolite pyocyanin [2].

The determination of the crystal structure of a key enzyme in the shikimate pathway from *P. aeruginosa* reveals a distinct regulatory mechanism and provides only the second example of a crystal structure of this type of enzyme.

Keywords or phrases (comma separated)

Are you a student?

Yes

Do you wish to take part in the Student Poster Slam?

Yes

Are you an ECR? (<5 yrs since PhD/Masters)

No

What is your gender?

Male

Primary author(s): Mr STERRITT, Oliver (University of Canterbury)

Co-author(s): Prof. PARKER, Emily (University of Canterbury); Prof. JAMESON, Geoffrey (Massey University)

Presenter(s) : Mr STERRITT, Oliver (University of Canterbury)

Track Classification : Structural Biology
